Evaluation of analgesic self-medication pattern among under-graduate medical students of Adichunchanagiri Institute of Medical Sciences, BG Nagar, Karnataka: a cross-sectional questionnaire-based study

Shwetha Shivamurthy, Ravishankar Manchukonda*, Deepika Gurappanavar

INTRODUCTION

In the developing countries, 60-80% of health problems are due to self-medication\(^1\) and the drugs are dispensed over the counter without medical supervision.\(^2\) There is an increase in the trend for self-care which resulted in self-medication with powerful drugs including drug combinations.\(^3\) People resort to self-medication since it’s a lower cost alternative for people who cannot afford the cost of clinical service. Studies have revealed that the increase in self-medication was due to a number of factors. These included socioeconomic factors, lifestyle, ready access to drugs, the increased potential to manage certain illnesses through self-care, and greater availability of medicinal products.\(^2\)

Analgesic self-medication is widely prevalent among undergraduate medical students. A study conducted at the All India Institute of Medical Sciences, New Delhi observed that self-medication was considerably high among undergraduate medical and paramedical students in India and it increased with medical knowledge.\(^4\)

Pain problems are important reasons for self-medication of analgesics. One of the most common complaints for the use of analgesic self-medication is headache. Around 25%
patients are not happy with the physician’s treatment for headache and 45% migraine patients do not take advice of physician for headache and take self-medications for relief of headache.

In India, there is a paucity of literature on the prevalence of analgesic self-medication especially among the young population who are highly influenced by media advertisements and internet which promote self-medication. This raises concerns of incorrect self-diagnosis, drug interactions, and use of drugs other than for the original indication. The present study was hence conducted to evaluate the prevalence of analgesic self-medication among the undergraduate students of Adichunchanagiri Institute of Medical Sciences (AIMS), BG Nagar with the following aims and objectives:
1. To find out the common health-related problems leading to self-medication with analgesics
2. To find out the commonly used analgesics
3. To find out the students’ attitude on self-medication and impact of pain on their quality of life.

METHODS

A cross-sectional observational study was carried out among the under-graduate students of AIMS during January-March 2014. A pre-designed semi-structured questionnaire was used to collect the relevant information pertaining to the study variables. The questionnaires were distributed to the medical under-graduates from the 1st, 2nd, 3rd, and 4th year of MBBS after obtaining ethical clearance from the Institutional Ethics Committee, AIMS, BG Nagar. The students were briefed on the aims and objectives of the study. The study subjects were informed that the information collected would be kept anonymous and participation would be totally voluntary.

The age, sex, and year of study of the students were noted. The information regarding: (1) type of medication, (2) type of illness for which the medication was used, (3) reason for not consulting a doctor, (4) their attitude toward self-medication, (5) source of information, (6) effect of pain on quality of life for those who practiced self-medication was recorded.

Totally, 218 students consented for the study out of 250 students and filled in the questionnaire. 20 incomplete questionnaires were excluded and the remaining 198 were analyzed. The questionnaires were assessed for their completeness and only the completed questionnaires were considered for the final analysis.

Ethical clearance was obtained from the Institutional Ethics Committee of AIMS, BG Nagar, Mandya district, Karnataka, India prior to the commencement of the study.

The results were expressed in numbers and percentage.

RESULTS

Our study showed 63.6% students of AIMS practiced self-medication. Female students (59.5%) outnumbered males (40.4%).

DISCUSSION

As per the World Health Organization, “self-medication is the selection and use of medicines by individuals to treat self-recognized illnesses or symptoms.” Self-medication is considered an element of self-care. In studies conducted within India, the prevalence of self-medication among the undergraduate medical students was shown to be ranging between 57.1% and 92%. Analgesics have been the most commonly used self-medication as seen in previous studies. Previous prescription experience with the illness was observed to be the most common reason for practicing self-medication (Table 2). Paracetamol is the most common drug being used as an analgesic (Table 1). Repeated consumption of paracetamol can cause adverse drug reactions like liver damage and drugs interactions like paracetamol toxicity if taken with alcohol/ other enzyme inducers due enzyme induction. Repeated use of other analgesics is associated with adverse renal effects and gastric ulceration or bleeding.

The prevalence of analgesic self-medication in our study was found to be 63.6%. In our study, headache was the most common reason for practicing self-medication (Table 2). Paracetamol is the most common drug being used as an analgesic (Table 1). Repeated consumption of paracetamol can cause adverse drug reactions like liver damage and drugs interactions like paracetamol toxicity if taken with alcohol/ other enzyme inducers due enzyme induction. Repeated use of other analgesics is associated with adverse renal effects and gastric ulceration or bleeding.

The most common reason for analgesic self-medication reported by students was the illness being too trivial (Table 4). Similar observations were reported in a few studies from India. However, in a study from Tamil Nadu most students practiced self-medication as it was time-saving, whereas in Punjab the most common reason for self-medication was for quick relief. Students are prone to make unsupervised health-related decisions especially the students of health sciences who feel confident of their knowledge about the drugs. In the present study, 39.1% of the participants indulged in self-medication owing to their sufficient pharmacological knowledge (Table 3). In studies from Ethiopia, Karachi, and Malaysia, prior experience with the illness was observed to be the most common reason for self-medication. Previous prescription for the same illness was reported as the most common source of information about the drugs used for self-medication in the present study, which was similar to the observation made in Tamil Nadu and Uttar Pradesh. However, in another study from India and Ethiopia textbooks were reported as the most common source of information analgesics are associated with adverse renal effects.
In the present study, 91.97% of the participants felt that self-medication was part of self-care (Table 6), which was higher to that reported in studies from Ethiopia\(^\text{21}\) and Karachi.\(^\text{22}\) Participants wished to continue with self-medication/start self-medication. They were even ready to advice self-medication to their friends.

The irrational use of drugs is a cause of public and professional concern. Self-medication as part of self-care can be justified only when there is a judicial use of medicines. There is always a risk of using expired drugs, sharing them with friends or taking medicine that have been originally prescribed for some other problem. Irrational use of drugs may result in accidental drug poisoning. Other problems related to self-medication are wastage of resources and serious health hazards such as drug dependence, adverse reactions, and prolonged suffering.\(^\text{25}\)

**CONCLUSION**

About 63.6% students of AIMS were practicing analgesic self-medication with paracetamol, diclofenac, aspirin etc., with mild nature of the illness being the most common cause. Although self-medication is an easy way to treat mild to moderate pain, it may be accompanied with side effects, drug interactions, and toxicities. Hence, we conclude that there is a need to create awareness and educate the undergraduate medical students regarding the possible harmful effects of self-medication with analgesics.

**ACKNOWLEDGMENTS**

We are thankful to the department of anatomy for enabling us to collect the data required during their dissection hours. We also thank the students of all the years for having voluntarily and enthusiastically participating in the questionnaire-based study.
